

Multinomial Processing Trees

Joachim Vandekerckhove

Spring 2025

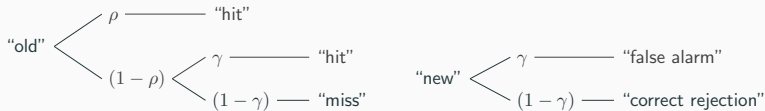

One-High-Threshold Model

The one-high-threshold model with parameters ρ (probability of remembering) and γ (probability of guessing “old”)

One-High-Threshold Model

The one-high-threshold model with parameters ρ (probability of remembering) and γ (probability of guessing “old”)

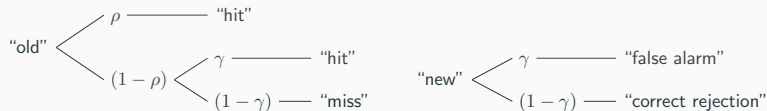

The tree representation shows the “flow” of the process

One-High-Threshold Model

The one-high-threshold model with parameters ρ (probability of remembering) and γ (probability of guessing “old”)

The tree representation shows the “flow” of the process

The parameters ρ and γ together determine the hit rate θ^h and false alarm rate θ^f

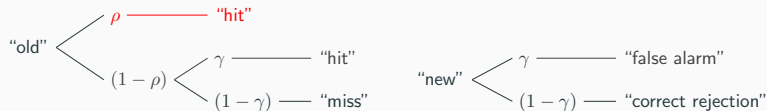

$$\theta^h = \rho + (1 - \rho) \gamma$$

$$\theta^f = \gamma$$

One-High-Threshold Model

The one-high-threshold model with parameters ρ (probability of remembering) and γ (probability of guessing “old”)

The tree representation shows the “flow” of the process

The parameters ρ and γ together determine the hit rate θ^h and false alarm rate θ^f

$$\theta^h = \rho + (1 - \rho) \gamma$$

$$\theta^f = \gamma$$

Weapon Priming Task

Effect of stereotypes on the identification of objects in a weapon-identification task

Weapon Priming Task

Effect of stereotypes on the identification of objects in a weapon-identification task

Participants presented with target images that they had to identify as a tool or a weapon

Weapon Priming Task

Effect of stereotypes on the identification of objects in a weapon-identification task

Participants presented with target images that they had to identify as a tool or a weapon

On each trial, the target image was preceded by one of three primes: an image of a white face, black face, or a neutral outline

Weapon Priming Task

Effect of stereotypes on the identification of objects in a weapon-identification task

Participants presented with target images that they had to identify as a tool or a weapon

On each trial, the target image was preceded by one of three primes: an image of a white face, black face, or a neutral outline

Half the 82 participants had 500ms to respond, and the other half had 1000ms

Weapon Priming Task

Effect of stereotypes on the identification of objects in a weapon-identification task

Participants presented with target images that they had to identify as a tool or a weapon

On each trial, the target image was preceded by one of three primes: an image of a white face, black face, or a neutral outline

Half the 82 participants had 500ms to respond, and the other half had 1000ms

We consider only the white and black face primes, and how people make decisions about the tool and gun targets in relation to the stereotype congruency and incongruency

Rivers et al. (2017) Data

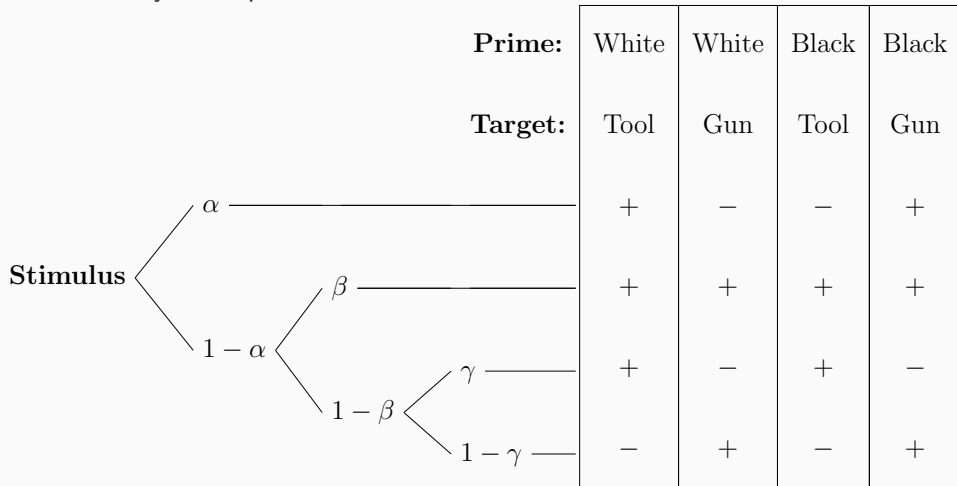

There were 1440 trials for each of the possibilities: white tool, white weapon, black tool, black weapon conditions \times two timing conditions

500ms	White	Black
Tool	885 (61%)	766 (53%)
Weapon	967 (67%)	1074 (75%)

1000ms	White	Black
Tool	1280 (89%)	1229 (85%)
Weapon	1281 (89%)	1288 (89%)

Weapon Priming MPT Model

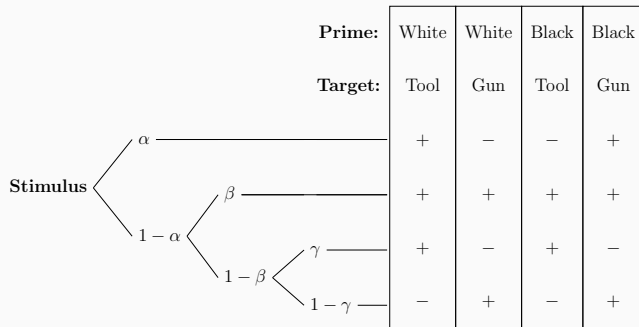

The “Stroop” model has sequential automatic, control, and guessing processes, controlled by three parameters

Weapon Priming MPT Model

The model involves three parameters, one for each process:

- a probability α of an automatic process that answers “tool” for a white face prime and “gun” for a black face prime
- a probability β of a control process that generates the correct answer
- a probability γ of guessing “tool”

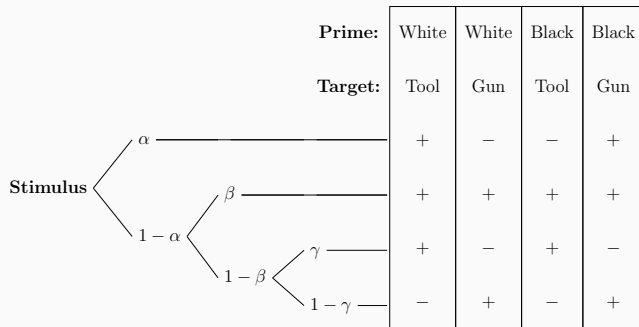

Weapon Priming MPT Model

$$\theta^{wt} = \alpha + (1 - \alpha) \beta + (1 - \alpha) (1 - \beta) \gamma$$

$$\theta^{bt} = (1 - \alpha) \beta + (1 - \alpha) (1 - \beta) \gamma$$

$$\theta^{wg} = (1 - \alpha) \beta + (1 - \alpha) (1 - \beta) (1 - \gamma)$$

$$\theta^{bg} = \alpha + (1 - \alpha) \beta + (1 - \alpha) (1 - \beta) (1 - \gamma)$$

Weapon Priming MPT Model

For data that have k^{wt} , k^{bt} , k^{wg} and k^{bg} correct responses out of n total trials, the model assumes that

$$k^{\text{wt}} \sim \text{binomial}(\theta^{\text{wt}}, n)$$

$$k^{\text{bt}} \sim \text{binomial}(\theta^{\text{bt}}, n)$$

$$k^{\text{wg}} \sim \text{binomial}(\theta^{\text{wg}}, n)$$

$$k^{\text{bg}} \sim \text{binomial}(\theta^{\text{bg}}, n)$$

The model also assumes all automatic and control rates are equally likely, and that guessing “tool” will happen around half the time:

$$\alpha \sim \text{uniform}(0, 1)$$

$$\beta \sim \text{uniform}(0, 1)$$

$$\gamma \sim \text{beta}(3, 3)$$

Key Points

The weapon-priming model is an example of an MPT model for addressing a social psychology phenomenon

Makes inferences about underlying executive control processes

The analysis of different deadline conditions in the experiment showed different use of automatic versus control processes
